

ABSTRACT

A light transmitting type screen that enables the viewer to see through to its back side, when the screen is stuck on a transparent object such as a show window or a transparent window glass or when it is used as a transparent object, and that is capable of forming clear images projected from a projector thereon is provided. The screen includes a light scattering layer having a front-scattering property, which is composed of spherical microparticles having a mean particle diameter in a certain range dispersed in a binder having a refraction index in a certain range. The light scattering layer is sandwiched between transparent objects such as high-molecular weight resin sheets or show window glass via an adhesive layer or the like.
